ARTHROSCOPIC SIMULATION: THE FUTURE OF SURGICAL TRAINING

A Systematic Review

Systematic Reviews

School, London, United Kingdom*

Abstract

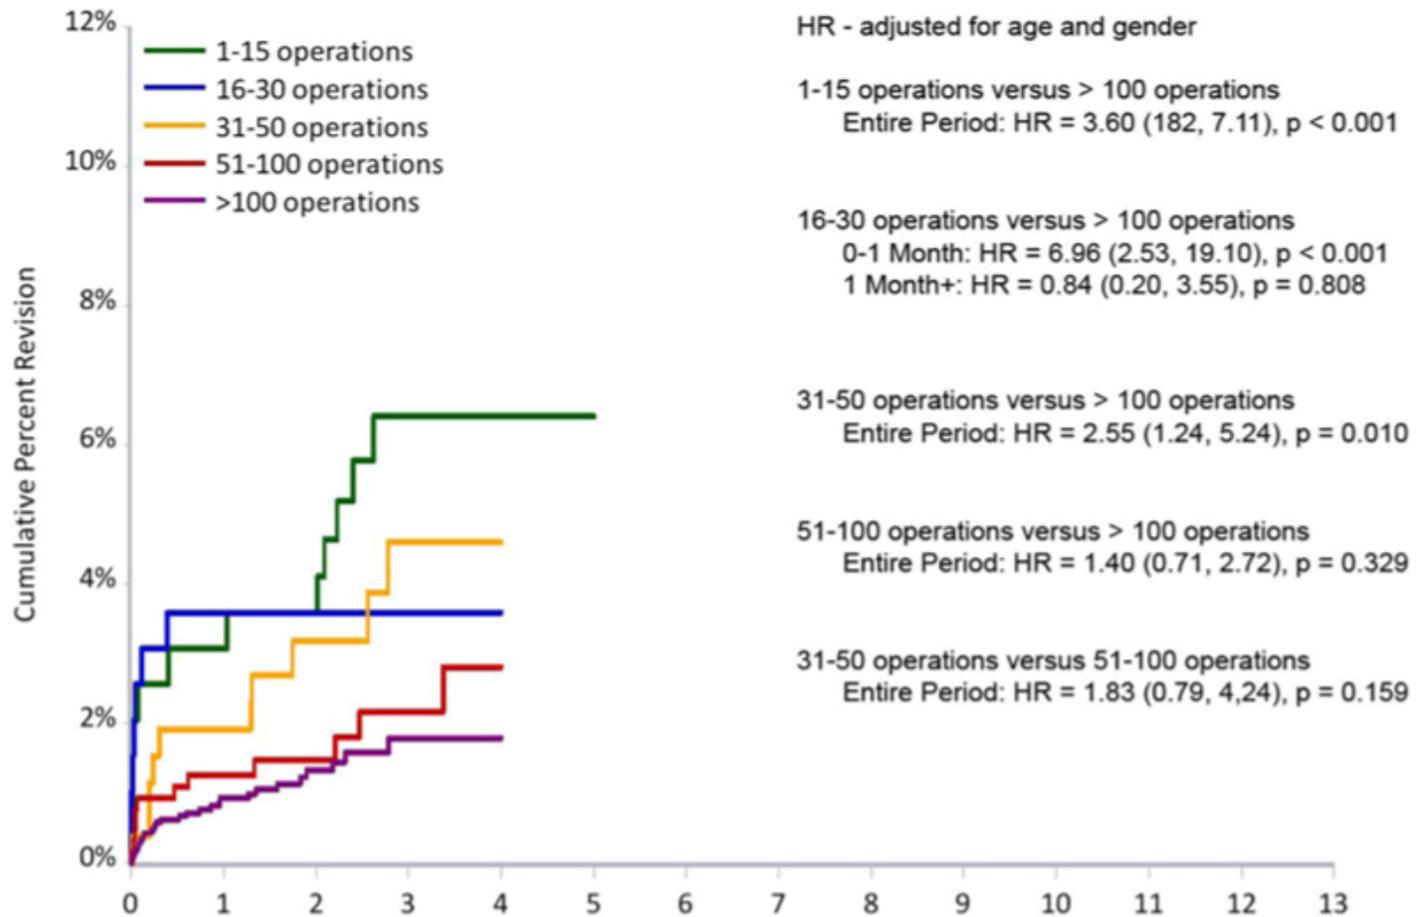

Background: Arthroscopic simulation has rapidly evolved recently with the introduction of higher-fidelity simulation models, such as virtual reality simulators, which provide trainees an environment to practice skills without causing undue harm to patients. Simulation training also offers a uniform approach to learn surgical skills with immediate feedback. The aim of this article is to review the recent research investigating the use of arthroscopy simulators in training and the teaching of surgical skills.

Methods: A systematic review of the Embase, MEDLINE, and Cochrane Library databases for English-language articles published before December 2019 was conducted. The search terms included arthroscopy or arthroscopic in combination with simulation or simulator.

Results: We identified a total of 44 relevant studies involving benchtop or virtually simulated ankle, knee, shoulder, and hip arthroscopy environments. The majority of these studies demonstrated construct and transfer validity; considerably fewer studies demonstrated content and face validity.

Conclusions: Our review indicates that there is a considerable evidence base regarding the use of arthroscopy simulators for training purposes. Further work should focus on the development of a more uniform simulator training course that can be compared with current intraoperative training in large-scale trials with long-term follow-up at tertiary centers.

Learning curve 1

For surgeons who have performed >100 procedures, revision rate reduced from 6% for the first 15 procedures to 2% after first 100.

Learning curve 2

Hip prosthesis introduction and early revision risk

A nationwide population-based study covering 39,125 operations

Mikko Peltola¹, Antti Malmivaara¹, and Mika Paavola^{1,2}

The **first 15 operations** with a new stem or cup model had an increased risk of early revision surgery.

The **risk of early revision** at the implementation phase should be considered when a new type of THA is brought into use.

Peltola Acta Orthop 2013

Operative Treatment in 120 Displaced Intraarticular Calcaneal Fractures

Results Using a Prognostic Computed Tomography Scan Classification

ROY SANDERS, M.D., PAUL FORTIN, M.D., THOMAS DiPASQUALE, D.O.,
AND ARTHUR WALLING, M.D.

When results were compared by year, a distinct learning curve appeared (Tables 3 and 4). The worst results occurred at the start of the series, whereas the number of excellent-good results improved each successive year (1987, 24%; 1988, 54%; 1989, 73%; 1990, 84%). When these data were further analyzed with respect to fracture type and year, it appeared that Type II articular fractures were easier to fix than Type III articular fractures. With time, even Type III results improved. Despite a better outcome for Type II and III articular fractures over time, however, the results of operative intervention in Type IV articular fractures were not improved on even after four years.

Errori di comunicazione

- Mancata comunicazione fra professionisti:
 - 24,7% degli errori in ortopedia (Wong 2009)
 - 48,6% degli errori di lato (Stahel 2010)
 - 100% degli errori di persona (Stahel 2010)

Communication Skills in Patient-Doctor Interactions: Learning from Patient Complaints

Janine W.Y. Kee^{a,*}, Hwee Sing Khoo^b, Issac Lim^b, Mervyn Y.H. Koh^c

Four main themes of communication errors were identified, namely: non-verbal (eye contact, facial expression and paralanguage), verbal (active listening and inappropriate choice of words), and content (poor quantity and quality of information provided); and poor attitudes (lack of respect and empathy)

The only effective and ultimately the only correct recommendation is to openly address the complication of PJI. The patient should be informed of the possibility of an infection as soon as possible and undergo appropriate diagnostic tests. This can only be done through an open and honest dialogue with the patient. Complaints are unnecessary and irrelevant, due to hygiene standards observed in most operating rooms around the world. As a rule, PJIs should be considered a random event. Responsibilities can be attributed to the surgeon or to the attending physician only in the case of delays or a wait-and-see approach to diagnostic outcomes and subsequent treatment. In a nutshell, the best thing is to be honest.

Parvizi and Gehrke cit in Basile 2021

Esempio di Classificazione in base al danno

- **Nessuno**, no harm (near miss)
- **Minore**, low harm (minimal harm—patient(s) required extra observation or minor treatment)
- **Moderato**, moderate harm (short-term harm—patient(s) required further treatment, or procedure)
- **Grave**, severe harm (permanent or long-term harm)
- **Morte**, death

A total of 257 incident reports were analysed. Four main thematic categories emerged. These were: (1) stages of the surgical journey – 118/191 (62%) of deaths occurred in the post-operative phase; (2) causes of patient deaths – 32% were related to severe infections; (3) reported quality of medical interventions – 65% of patients experienced minimal or delayed treatment; (4) skills of healthcare professionals – 44% of deaths had a failure in non-technical skills

Litigations in orthopedics and trauma surgery: reasons, dynamics, and profiles

Martin Gathen¹ · M. Jaenisch¹ · F. Fuchs¹ · L. Weinhold² · M. Schmid² · S. Koob¹ · D. C. Wirtz¹ · M. D. Wimmer¹

Our results could not confirm the often-stated trend of having more litigations against orthopedic and trauma surgeons. Although the absolute numbers increased, the number of litigations per 1000 patients treated declined. Patients who underwent elective surgery were more likely to file complaints than emergency patients.

Impatto sui Chirurghi Ortopedici (infezioni: 0.5-3% primo impianto 20% revisioni)

RESEARCH ARTICLE

Surgeons are deeply affected when patients are diagnosed with prosthetic joint infection

Charlotte Mallon¹, Rachael Gooberman-Hill^{1,2}, Ashley Blom^{1,2}, Michael Whitehouse^{1,2}, Andrew Moore^{1*}

The impact is shown to be greater when the complication is unexpected, results from elective surgery and leads to severe disability [14]. Such events can lead to intense emotional responses, impaired decision making, difficulty concentrating, a negative impact on clinical judgement and deleterious changes to practice [9,10]. The cumulative effect of these reactions may potentially impact upon surgeons' personal and professional identities [10], and lead to a greater risk of error and suboptimal patient care [34]. Evidence suggests that surgeons may become increasingly conservative and risk-averse in response to these events [14], potentially reducing access to care for high-risk patients.

Between good and best, maybe we can settle for *better*...

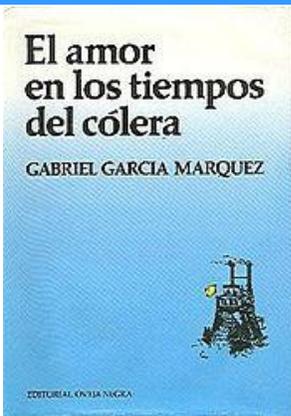

BMJ 2002;324:859-860 (13 April)

Editorials

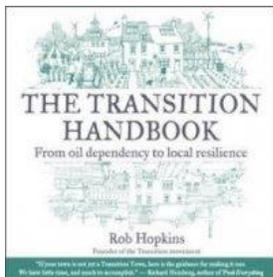

Too much medicine?

Almost certainly

- Less Rituals, transparent and judicious use of shortcuts
- Simplify «digestion» of large data
- Fight fake-news and anti-scientific thinking
- Be aware of financial interests and defensive medicine
- Avoid Harms
- Engage in registration, quality monitoring ecc.

- **Errors** aren't our sole problems
 - End of the low-cost fossil fuel Era
 - Climate Changes
 - Economic (& moral) Crises
 - Wars for resources
- We need to De-grow and start the Transition...

Cosa ci serve davvero?

“Politics rather than promising paradise should avoid hell”
(Mario Giro)

AFS – Intercultura centennial meeting
Trento e Rovereto May 1-3 2015

Evitare l'inferno

There are certainly cases of gross misconduct and malpractice, and we must always protect our patients. We should neither apologize for nor excuse inappropriately performed surgeries. It is our professional, ethical, and moral duty to regulate surgeons who may routinely cause harm due to negligence or poor skill. However, poor patient outcomes occur at the hands of excellent surgeons as well, and we should always remember that the vast majority of orthopedic surgeons carry with them the same desire to do well by their patients and provide excellent care. We challenge you to take into account all these considerations when speaking to patients about their previous orthopedic care.

Orthopedics in Glass Houses

John Y. Kwon, MD¹, and Christopher P. Miller, MD¹

When you judge others, you do not define them, you define yourself.

Wayne Dyer

“We got another disaster from the outside hospital,” my resident reported (Figure 1). “Does this guy know anything about ankle fractures?” Upon examining the radiograph I paused to consider the situation that the surgeon may have found himself in. But what do I tell my patient? What lessons can my resident learn?

Much has been written regarding the disclosure of medical errors to patients, and there is increasing literature regarding disclosure of errors made by one’s colleagues. Gallagher et al recently convened a panel of experts from various fields including patient safety, malpractice law, bioethics, and health policy and published various recommendations for disclosure of a fellow clinician’s harmful errors.¹ The authors recommended improved colleague-to-colleague communication and transparent disclosure of errors as a shared professional responsibility with a collective approach to accountability.

Although the same ethical, moral, and legal issues apply regardless of medical subspecialty, the field of orthopedic surgery has unique considerations. Although the detection of substandard care in other specialties may require exhaustive examination of the medical record, often a single radiograph is all that is required in our field.

The assessment we make of a *radiograph* for healing, alignment, positioning of implants, etc is a by-product of our orthopedic training. It doesn’t take much time to determine what was done, how well (or poorly) it was performed, and prognosticate on outcomes. However, the assessment we make of the *surgeon* who performed the surgery is a far more complex process and often subconscious in nature. During our weekly trauma rounds, I occasionally hear a trainee denounce a surgeon when examining a poor radiographic outcome, especially when performed at the well-known “outside” hospital. “Bad” surgeon (or usually a more descriptive term) is often what is said. However, although “bad” surgery may be closer to the truth of things at times, usually there is more to the story. In this context, for the sake of collegiality, consider the following when examining a colleague’s work.

Resources

Great operative outcomes require a cohesive operative team doing a lot of complex tasks properly, all at the same time.

Figure 1. Ankle Radiograph.

Whether it be staff or equipment, other surgeons may simply not have access to resources that you have readily available and may take for granted.

When we fix ankle fractures at our institution, we can choose from 5 different ankle fracture plating systems. We operate with a senior Harvard orthopedic resident or fellow in combination with a dedicated orthopedic OR team. Additionally, we’ve had the opportunity to train with some of the greatest surgeons in the world. We better get it right, and most of the time we do. However, even with all of these available resources, sometimes

Increased risk of intraoperative and early postoperative periprosthetic femoral fracture with uncemented stems

7,169 total hip arthroplasties from 8 Danish centers

Martin LINDBERG-LARSEN^{1,2}, Christoffer C JØRGENSEN^{3,2}, Søren SOLGAARD^{4,2}, Anne G KJERSGAARD^{4,2}, and Henrik KEHLET^{3,2}. On behalf of the Lundbeck Foundation Centre for Fast-Track Hip and Knee Replacement Collaborative Group⁵

Results — Of 7,169 primary consecutive THAs, 5,482 (77%) were performed using uncemented femoral components. The total incidence of periprosthetic femoral fractures \leq 90 days postoperatively was 2.1% (n = 150). 70 fractures were detected intraoperatively (46 required osteosynthesis). 51 postoperatively detected fractures occurred without trauma (42 of which were reoperated) and 29 were postoperative fall-related fractures (27 of which were reoperated). 134 fractures (2.4%) were found in uncemented femoral components and 16 (0.9%) were found in cemented femoral components (p < 0.001). Uncemented femoral stem (relative risk (RR) = 4.1, 95% CI: 2.3–7.2), medically treated osteoporosis (RR = 2.8, CI: 1.6–4.8), female sex (RR = 1.6, CI: 1.1–2.2), and age (RR = 1.4 per 10 years, CI: 1.2–1.6) were associated with increased risk of periprosthetic femoral fracture when analyzed using multivariable regression analysis.

Lack of evidence—the anti-stepwise introduction of metal-on-metal hip replacements

A systematic review and a comparative assessment of the literature and registry data

Aleksi REITO¹, Lari LEHTOVIRTA^{1,2}, Olli LAINIALA¹, Keijo MÄKELÄ³, and Antti ESKELINEN¹

The very foundation of current health care management is to have a robust, evidence-based approach, characterized by the promotion of unbiased, highly reliable types of evidence.

Any innovation should work under ideal circumstances (“can it work?”) as well as the usual circumstances (“does it work in practice?”).

Unfortunately, orthopedics and especially the field of joint replacement surgery have had more than their fair share of **unsuccessful innovations that have violated these principles.**

Innovazioni di successo: sutura artroscopica di cuffia

Linee Guida SICSeG

Il trattamento chirurgico delle rotture della cuffia dei rotatori in età adulta

BOX 2. Sulla chirurgia artroscopica nel trattamento delle lesioni della cuffia dei rotatori.

La sutura artroscopica della cuffia dei rotatori è stata proposta la prima volta nel 1980 ma ha preso piede negli anni '90, rivoluzionando il modo di approcciarsi alla chirurgia della spalla. Dopo lo scetticismo iniziale, oggi nessun chi-

ministratori, policy maker e pazienti) di sottoscrivere – separatamente dalle evidenze scientifiche – la seguente **PRESA DI POSIZIONE** (*Raccomandazione Forte, ma basata sul consenso di esperti*):

- **Si raccomanda di prendere in considerazione solamente la chirurgia artroscopica quale tecnica di prima scelta per la riparazione routinaria delle lesioni della cuffia dei rotatori, fatta eccezione per le lesioni isolate del sottoscapolare o lesioni massive che richiedano interventi comunque differenti dalla semplice sutura (trasposizioni tendinee, protesi ecc.).**
- **La tecnica a cielo aperto (nella sola accezione mini-open) deve essere considerata una tecnica di salvataggio per casi eccezionali e non può essere in nessun caso posta come indicazione elettiva di partenza. I chirurghi che intendano affrontare la patologia della cuffia dei rotatori devono necessariamente avere padronanza della tecnica artroscopica.**
- **Le strutture pubbliche e private dove si effettuano interventi di riparazione della cuffia dei rotatori devono necessariamente dotarsi di strumentazione artroscopica specifica per la spalla e assicurarsi che i chirurghi siano sufficientemente competenti nella metodica.**
- **In nessun modo la scelta di effettuare la chirurgia artroscopica deve comportare una perdita economica in termini di DRG, essendo peraltro più dispendiosa come utilizzo di materiali di consumo pur in assenza di differenze globali in termini di analisi costi-efficacia. Si invitano i sistemi sanitari regionali ad armonizzare le tariffe nel rispetto di una corretta codifica.**

Robotica

- Conflitti di interesse

- Of the 54 studies meeting inclusion criteria, 49 (91%) had an author financial COI. Conflicted studies were more likely to report favorable results of robotics than nonconflicted studies.

- Dati da Registro Australiano

- + 34,2% nel 2020
- Restoris MCK 4,2 % di revisione a 5 anni
- Migliore UKR: 4,7%
- Migliori TKR: 2%
- Maggior rischio di revisione per infezioni

Qui viene
il bello.

(This is the good stuff.)

Six proposals for EBM's Future

1. Don't skip "step 0", but foster doubt, **uncertainty** and honesty
2. Beware overdiagnosis: our definitions are as important as our tests
3. It is the patient's decision: practise and teach Shared Decision Making alongside EBM
4. **Take non-drug interventions as seriously as pharmaceuticals**
5. Build clinical practice "laboratories" to study translation and uptake
6. Invest long-term in automating evidence synthesis

Glasziou, BMJ Clinical Evidence 2015

The IDEAL Collaboration

Idea, Development, Exploration, Assessment, Long-term follow-up

Table 1. Defining characteristics of IDEAL framework phases

Phase 1 IDEA	Phase 2a DEVELOPMENT	Phase 2b EXPLORATION	Phase 3 ASSESSMENT	Phase 4 LONG TERM MONITORING
Initial report Innovation may be planned, accidental or forced Focus on explanation and description	“Tinkering” (rapid iterative modification of technique and indications) Small experience from one centre Focus on technical details and feasibility	Technique now more stable Replication by others Focus on adverse effects and potential benefits Learning curves important Definition and quality parameters developed	Gaining wide acceptance Considered as possible replacement for current treatment Comparison against current best practice	Monitoring late and rare problems, changes in use

Table 2. Key recommendations for research design at each IDEAL phase

IDEA <i>Professional Innovation Database</i>	DEVELOPMENT <i>Prospective Development Studies</i>	EXPLORATION <i>Phase IIS Study</i>	ASSESSMENT <i>Surgical RCT</i>	LONG TERM MONITORING <i>Prospective Registries</i>
Compulsory reporting of all new innovations Confidential entry allowed to encourage reporting of failed innovations (similar to CHRP system) Hospital or institution to be informed separately as a professional duty	Detailed description of selection criteria Detailed technical description Prospective account of ALL cases consecutively, including those NOT treated with new technique/device Clear STANDARDISED definitions of outcomes reported Description of ALL modifications, and when they were made during the series Registration of PROTOCOL before study starts Use of Statistical Process Control (SPC) methods to evaluate progress	To evaluate technique prospectively and co-operatively To develop a consensus over <i>definition</i> of the procedure, <i>quality</i> standards and <i>indications</i> To gather <i>data</i> for <i>power calculations</i> To evaluate and monitor <i>learning curves</i> To achieve consensus on the <i>trial question</i> To develop a <i>multi-centre randomised trial (RCT)</i>	RCT – question agreed in Phase IIS Use power calculations from Phase IIS Use learning curve data to decide entry points for clinicians Use Phase IIS consensus to define operation, quality control AND outcome measures Use modified RCTs or recognised alternative if RCT not feasible: Feasibility RCT Expertise-based RCT Cohort multiple RCT Step-wedge design Controlled-interrupted time series	Should monitor indications as well as outcomes SPC used for quality control (Shewart charts, CUSUM, VLAD)

20	27814	Open treatment of bimalleolar ankle fracture, including internal fixation	1219 (1.20%)
21	27792	ORIF of distal fibular fracture (lateral malleolus), including internal fixation	1018 (1.00%)
22	29807	Arthroscopy, shoulder, surgical; repair of slap lesion	997 (0.98%)
23	23412	Repair of ruptured musculotendinous cuff (eg, rotator cuff), open; chronic	929 (0.91%)
24	27235	Percutaneous skeletal fixation of femoral fracture, proximal end, neck	882 (0.87%)
25	63075	Discectomy, anterior, cervical, single interspace	864 (0.85%)
26	27486	Revision of TKA, with or without allograft; 1 component	846 (0.83%)
27	23470	Arthroplasty, glenohumeral joint; hemiarthroplasty	749 (0.74%)
28	29806	Arthroscopy, shoulder, surgical; capsulorrhaphy	742 (0.73%)
29	22554	Arthrodesis, anterior interbody technique, including minimal discectomy to prepare interspace, cervical below C2	716 (0.70%)
30	22630	Arthrodesis, posterior interbody technique, including laminectomy and/or discectomy to prepare interspace, single interspace; lumbar	707 (0.69%)

CPT[®] = Current Procedure Terminology; ORIF = open reduction and internal fixation.
